

# Object-Oriented Programming

Introduction to Java

# Contents

- Brief history of Java
- Java platforms and applications
- Writing your first java program
- Compile and run your first Java program
- Code structure
- Basic data types and operators
- Loop control and decision making

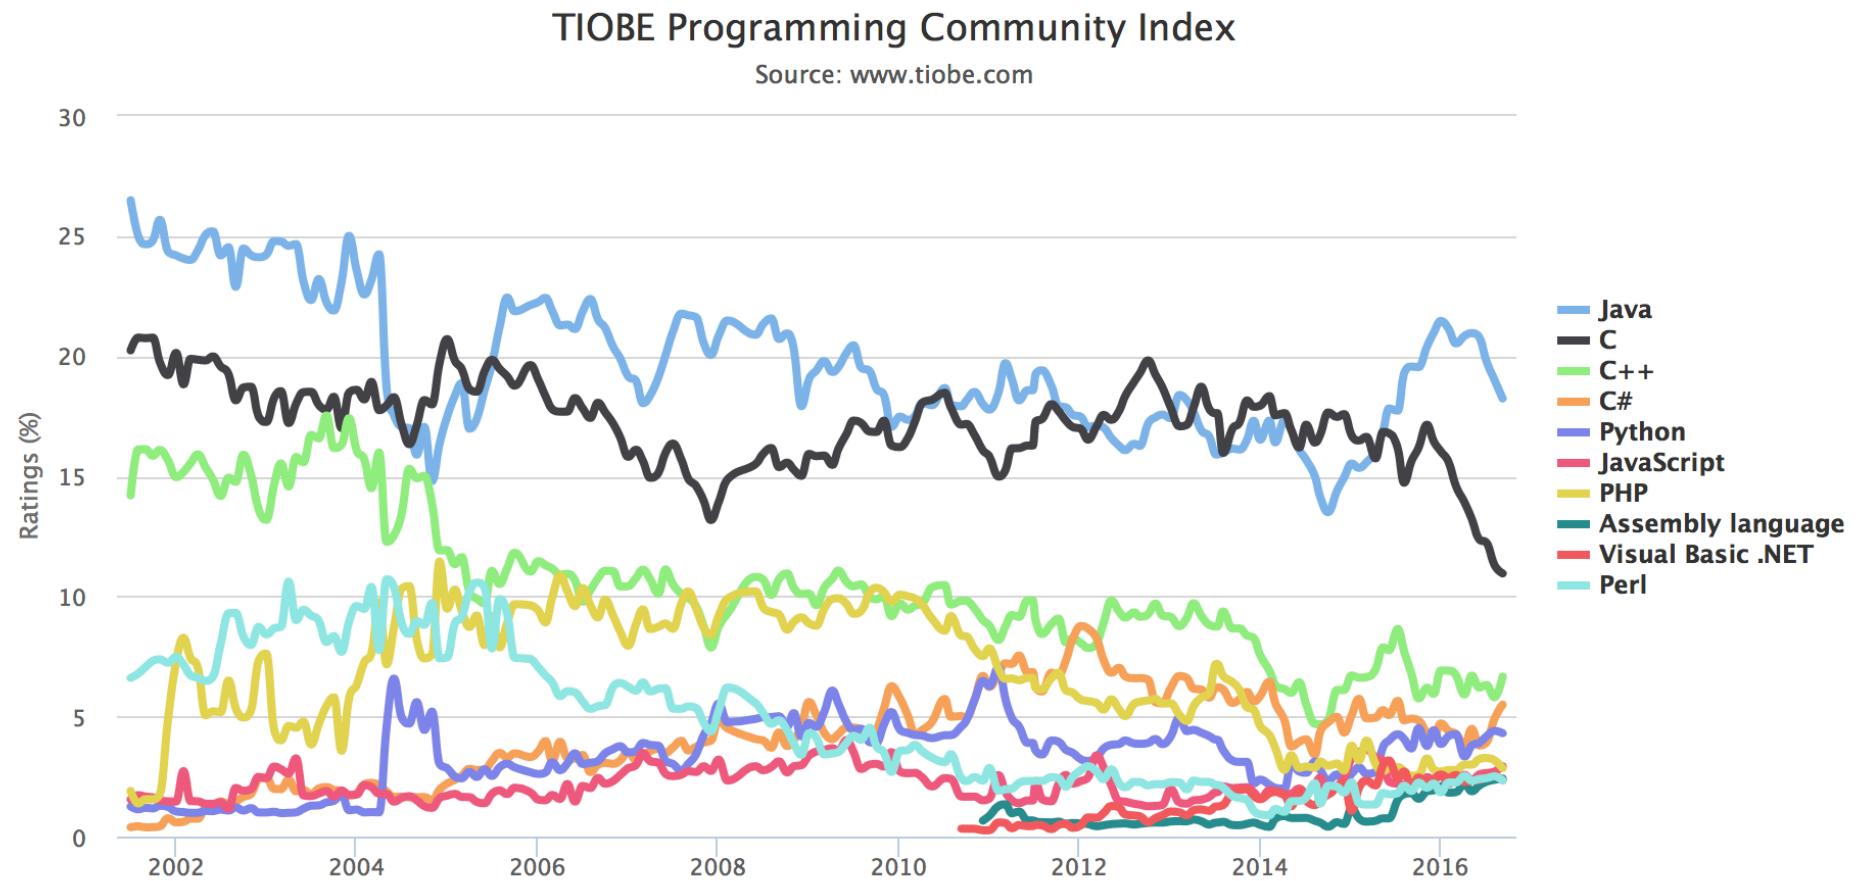

# History of Java

- 1991: developed by Sun Microsystems as a small programming language for embedded household devices
  - initially called Oak
- Java 1.0.2 (1996), Java 1.1 (1997)
  - “[Write Once, Run Anywhere](#)”
  - very slow
  - became popular with Web pages running Applets
- Java 2 (versions 1.2 – 1.4 from 1998-2002)
  - much faster, powerful
  - 3 platforms:[J2SE](#), [J2EE](#), [J2ME](#)
- Java 5,6,7,8 (versions 1.5 – 1.8 in 2004, 2006, 2011, 2014)
  - more powerful

# Java Platforms and Applications

- Desktop Applications - **Java Standard Edition (J2SE)**
  - Java Application: normal Java application running on desktops; console or GUI
  - Java Applet: embedded application running within Web browsers
- Server Applications - **Java Enterprise Edition (J2EE)**
  - Web Services, JavaServer Pages (JSP), Servlet
- Mobile Applications - **Java Micro Edition (J2ME)**

# Why Java?

# Installing Java

- Download and install **Java Development Kit (JDK)** on Windows, Linux or Mac OS

<http://www.oracle.com/technetwork/java/javase/downloads/index.html>

- Remember to set PATH

# Java Development Kit (JDK)

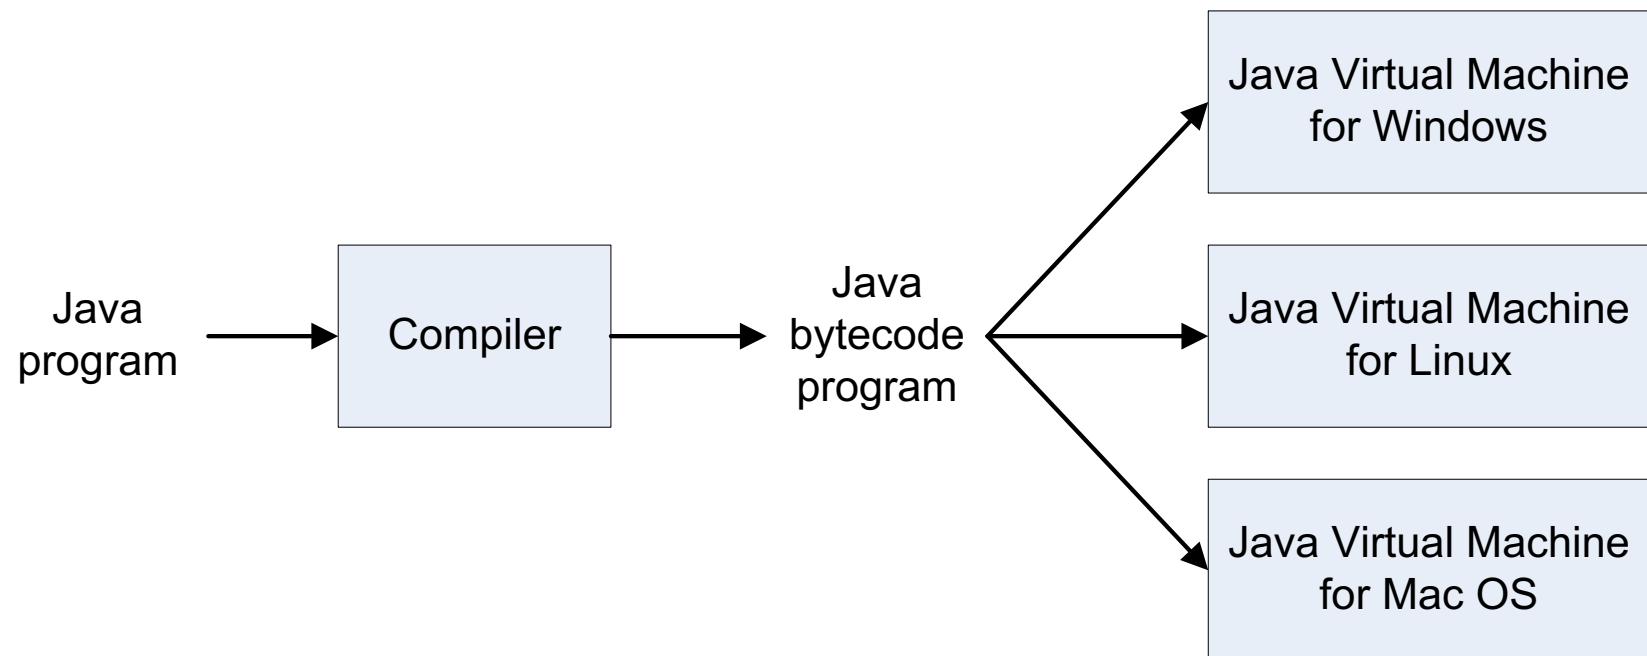

- Free development and run-time environment
- Main components:
  - **javac** : compiler, converts source code into Java bytecode
  - **java** : interpreter and application loader
  - **javadoc** : documentation generator, automatically generates documentation from source code comments
  - **jdb** : debugger

# Java Editor/IDE

- Editor and Integrated Development Environment (IDE):
  - Notepad, EditPlus, Notepad++
  - Eclipse
  - NetBeans
  - IntelliJ Community Edition is recommended
- Build tool:
  - Gradle
  - Maven is recommended

# Running Java Codes

- Java source code is compiled into bytecode
- Bytecode is executed in an interpreter environment, called **Java Virtual Machine**

# Java Virtual Machine (JVM)

- Provide Java programs with run-time environments
- Normally provided as software:  
**JRE: Java Runtime Environment**
- Depend on specific hardware and OS
- Java platform: JVM + APIs (Application Programming Interface)

# Writing your first Java program

- In Java, everything goes in a **class**
- When you run a program, you run a class:
  - load the class then start executing the class's main() method
  - Each Java program MUST have a main() method

# Writing your first Java program

*file name and class name are identical*

**HelloWorld.java:**

```
public class HelloWorld {  
    public static void main (String[] args) {  
        System.out.println("Hello, world");  
    }  
}
```

*this is a class*      *class name*      *start of the class*

*method name*

*a statement*  
*A function call that prints  
the text "Hello, world"  
to the standard output*

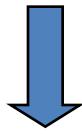

*end of the class*

The diagram shows the Java code for a 'HelloWorld' application. A green dashed box encloses the entire code. Annotations with arrows point to specific parts: 'HelloWorld.java:' points to the file name; 'this is a class' points to the 'public class' declaration; 'class name' points to 'HelloWorld'; 'start of the class' points to the opening brace '{' of the class definition; 'method name' points to the 'main' method; 'a statement' and its detailed description ('A function call that prints the text "Hello, world" to the standard output') point to the 'System.out.println' line; 'end of the class' points to the closing brace '}' of the class definition. The word 'public' is highlighted in green.

*public, so that everyone can  
access the main method of  
the class HelloWorld*

# Compile and Run your first program

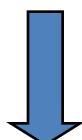

```
// Java source code is stored in the file HelloWorld.java
public class HelloWorld {
    public static void main (String[] args)
    {
        System.out.println("Hello, world");
    }
}
```

 To compile `HelloWorld.java`,  
type **javac HelloWorld.java**

compile

**HelloWorld.class**

 To run `HelloWorld.main()`,  
type **java HelloWorld**

run

```
%> javac HelloWorld.java
%> java HelloWorld
Hello, world
```

# Code Structure

```
public class Car {  
    void break() {  
        statement_1;  
        statement_2;  
    }  
  
    void turn_right() {  
    }  
}
```

source file **Car.java**  
*each file holds one class*

**class Car**  
*a class has one or more methods*

**statements**  
*statements are inside methods*

**two methods of class Car**  
*methods belong to a class*

# Application with more than one class

Two classes are stored in two separated files:

TestGreeting.java:

```
public class TestGreeting {  
    public static void main(String[] args) {  
        Greeting gr = new Greeting();  
        gr.greet();  
    }  
}
```

Greeting.java:

```
public class Greeting {  
    public void greet() {  
        System.out.print("Hi there!");  
    }  
}
```

# Compile and Run

- **Compile**

`javac TestGreeting.java`

- `Greeting.java` is automatically compiled

- **Run**

`java TestGreeting`

```
%> javac TestGreeting.java
```

```
%> java TestGreeting
```

```
Hi there!
```

# Basic Data Types

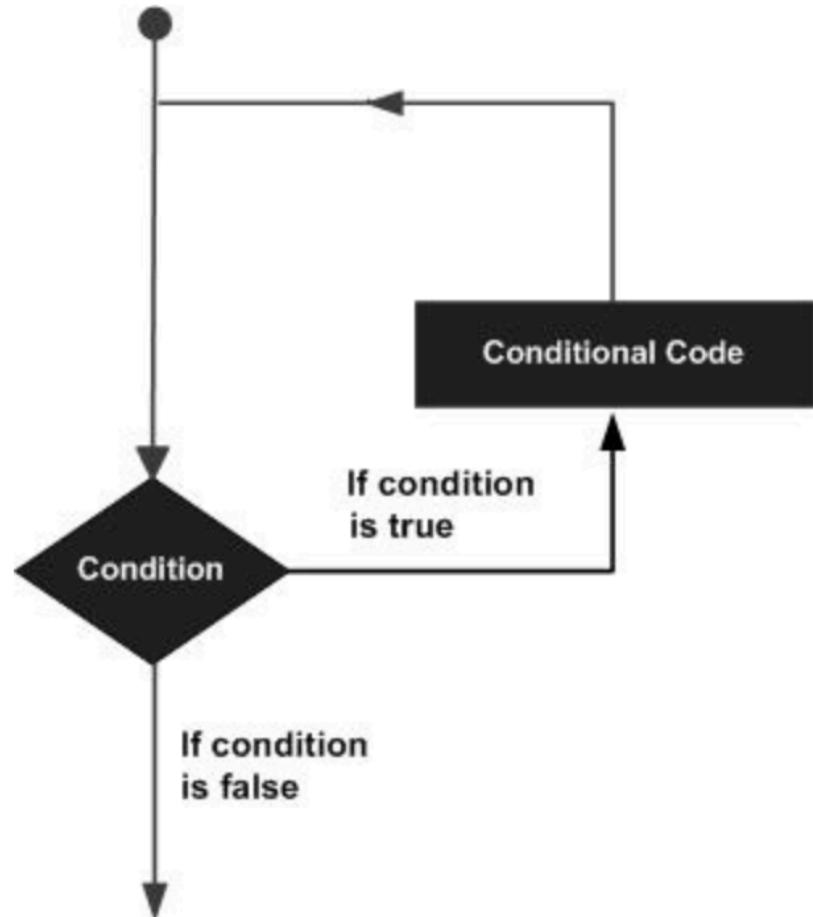

Data Type	Default Value	Default size
boolean	false	1 bit
char	'\u0000'	2 byte
byte	0	1 byte
short	0	2 byte
int	0	4 byte
long	0L	8 byte
float	0.0f	4 byte
double	0.0d	8 byte

# Basic Operators

Operator	Type
<b>unary operator</b> → <code>++</code> , <code>--</code>	Unary operator
<b>Binary operator</b> { <code>+</code> , <code>-</code> , <code>*</code> , <code>/</code> , <code>%</code> <code>&lt;</code> , <code>&lt;=</code> , <code>&gt;</code> , <code>&gt;=</code> , <code>==</code> , <code>!=</code> <code>&amp;&amp;</code> , <code>  </code> , <code>!</code> <code>&amp;</code> , <code> </code> , <code>&lt;&lt;</code> , <code>&gt;&gt;</code> , <code>~</code> , <code>^</code> <code>=</code> , <code>+=</code> , <code>-=</code> , <code>*=</code> , <code>/=</code> , <code>%=</code>	Arithmetic operator Relational operator Logical operator Bitwise operator Assignment operator
<b>Ternary operator</b> → <code>?:</code>	Ternary or conditional operator

# Loop Control Statements

- while loop
- for loop
- do...while loop

# Example of While Loop

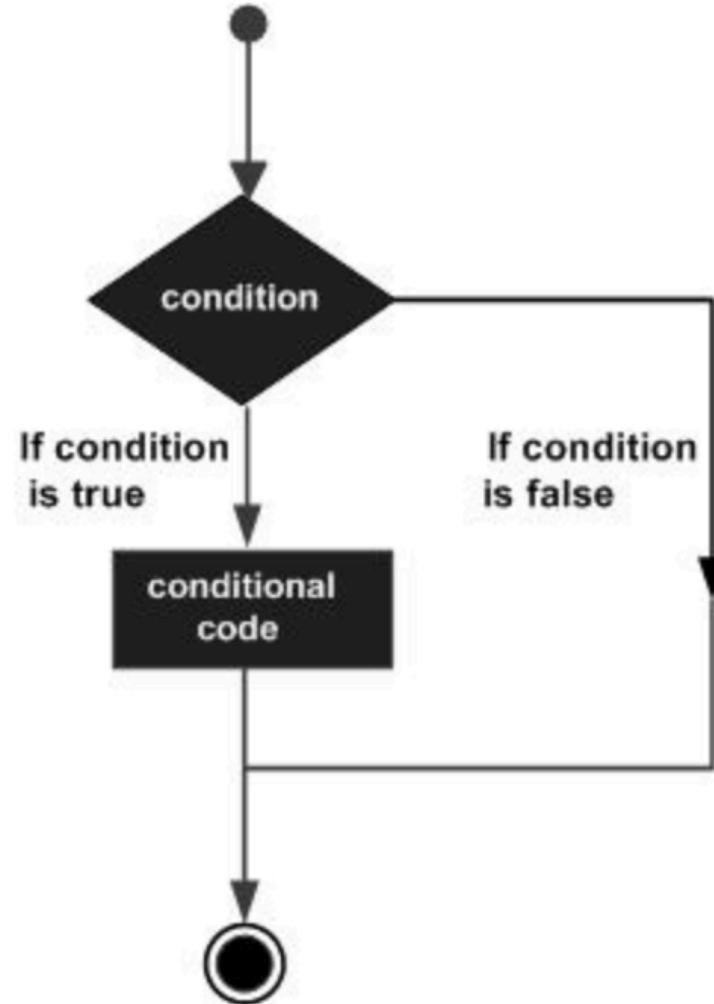

```
class WhileLoopExample {  
    public static void main(String args[]){  
        int i=10  
        while(i>1){  
            System.out.println(i);  
            i--;  
        }  
    }  
}
```

# Example of For Loop

```
class ForLoopExample {  
    public static void main(String args[]){  
        for(int i=10; i>1; i--){  
            System.out.println("The value of i is: "+i);  
        }  
    }  
}
```

# Decision Making Statements

- if statement
- if...else statement
- switch statement

# Example of If Statement

```
public class IfStatementExample {  
    public static void main(String args[]){  
  
        int x = 5;  
  
        if (x == 2) {  
            System.out.println("x must be 2");  
        } else {  
            System.out.println("x is not 2");  
        }  
    }  
}
```

# What else can we do?

- do-while?
- switch?
- int, long, float, double, boolean,...?
- other Java basics?

Read the text books!
